Government-Funded Green Banks: Catalysts for the Green Transition^{*}

Claudio Rizzi[†], Simon Xu[†], and Paul Yoo[§]

Abstract

The Inflation Reduction Act (IRA) allocated \$27 billion to the Greenhouse Gas Reduction Fund to funnel financing for clean energy and climate solutions. Government-funded Green Banks are delegated to administer the fund with a view to attract and amplify private capital investment in reducing emissions. In this paper, we examine the efficacy of Green Banks on mobilizing local investment in the context of climate-related startups. Pre- and post-introduction of IRA in Congress, we show a significant increase in venture capital deals and the total investment amount for local climate-related startups in counties where a Green Bank has issued loans. Our evidence is consistent with Green Banks de-risking climate ventures to facilitate a bottom-up green transition.

JEL Classification: G23, G28, O44. **Keywords:** Green banks, climate tech, renewable energy, green transition.

1. Introduction

The increasing frequency and severity of natural disasters due to global warming have raised awareness regarding the financial costs of climate change and the extent to which markets account for environmental risks. Recent analyses estimate that achieving the 1.5°C global warming target will require \$4.5 trillion in clean energy investments annually, yet current investments fall short by \$2.7 trillion (International Energy Agency, 2023). This funding gap highlights the urgent need to develop innovative financial mechanisms and policies that bridge this divide, with implications for both government-led and market-driven investment strategies. This gap is at the center of the upcoming COP29, so much so for the conference to be known as the "finance COP". Specifically, the aim for COP29 is to "advance a range of financial tools and instruments to support actions to address climate change". As global policymakers convene to define sustainable finance pathways, the pivotal role of climate finance—through both public and private capital—has never been more apparent.

In response to this funding gap, the U.S. recently introduced the Greenhouse Gas Reduction Fund (GGRF) within the Inflation Reduction Act (IRA), a \$27 billion initiative designed to mobilize both private and public capital to accelerate the transition to a low-carbon economy. The GGRF seeks to promote energy independence, ensure U.S. competitiveness, and lower energy costs in socio-economic minority communities. This fund will be deployed through Green Banks (GBs), government-funded mission-driven institutions that leverage innovative financing to catalyze green investment and help bridge the climate funding gap. Thus, GBs act as pivotal financial intermediaries, directing funds toward sustainable projects aimed at reducing greenhouse gas emissions. The GGRF exemplifies the type of blended finance model that COP29 aims to advance, wherein government seed capital draws in private investors to address shared environmental and economic goals. As green finance mechanisms expand, understanding how different deployment strategies affect private investment in green projects is essential to guide governments investment strategies.

In this paper, we first describe the government-funded GBs and investigate whether their financing activities substitute or complement existing private capital investment in local climate-focused startups. To this end, we center our analyses on venture capital (VC) investment in these startups and study how the onset of GB lending spurs it. This particular setting offers several advantages for identification. First, because GBs seldom directly provide capital to startups, it allows us to assess "additionality" of GB financing to novel and risky climate projects.¹ Relatedly, the GGRF mandates grant recipients (i.e., GBs) to support only commercial technologies—classes of technologies that have been deployed for commercial purposes.² The mandate preserves GBs' focus on existing technologies and limits direct intermediation to startups. Finally, our data source for VC activities, Pitchbook, distinguishes between climate- and non-climate-related startups into distinct categories, so enables us to control for overall startup activity.

Furthermore, the choice of examining the association between VC investment in climate startups and GB operation lets us hone in on plausible mechanisms through which GBs could unlock VC investment. VCs, including impact funds, are profit-driven and among the least likely asset managers to sacrifice returns for non-financial purposes (see Geczy, Jeffers, Musto, and Tucker (2021) and Jeffers, Lyu, and Posenau (2024), for example). Therefore, VCs would reassess their portfolio of startups only if they believe a GB funding availability alters the financial prospect of climate startups. As mentioned before, because not much of GB funds have arguably been directed to climate startups, if VC deals occur more likely for climate than non-climate startups in a county after it receives GB funding, then it implies VCs interpret GB lending activity in the county as a convincing signal that an investment in residing climate startups is more likely to financially payoff.³ Among others would the signal entail certifying a robust governmental backing and a stable flow of public funding for climate startups to maintain or gain momentum for growth.

Indeed, our main results indicate that GB activity significantly boosts VC investment in local climate-tech startups. Using a generalized staggered difference-in-differences (DiD) approach over the sample period from 2015 to 2023, we find that counties receiving at least one GB loan experience an increase of 8.5% to 11.6% in climate startup VC deals over the four years following the loan. The results are robust to different fixed effects specifications, which account for time invariant startup unobservables as well as time-variant industry and county unobservables. In addition, using a dynamic DiD approach, we cannot reject the parallel-trends assumption, which suggests that local pre-trends do not drive the results. We hypothesize that the introduction of the GGRF within the IRA provide a substantial signal of the availability of funds for investment in the green transition through GBs. We find that

¹Some GBs offer small seed investments and grants to startups through incubators. However, these investments are limited to very few banks and involve minimal investment volumes. For instance, in 2010, the Maryland Clean Energy Center launched the Clean Energy Technology Incubator and Innovation Network. As of October 2024, this incubator hosted 21 startups.

²The detailed definition of commercial technologies can be found at this link.

³Even if the startups in our sample consist of those deploying commercial technologies, the investment of GBs into the startups is trivial in size vis-à-vis that of VCs.

after the IRA was introduced in congress, VC funding of climate-related startups increased in counties that received GB loans. Conditional on the presence of GBs in a given county, the deliberation of the IRA sufficed for VCs to expect investments in climate startups in the county to be more profitable. The fact that an increase in VC deals is observed even when the IRA is still in the works rationalizes the signaling mechanism.

We further investigate whether the impact of GB loans on VC investment is heterogeneous across different types of startups and regions in the U.S. Our cross-sectional tests show that the effect of GB activity is most pronounced for older climate-tech startups and those with prior VC financing. This finding aligns with the mandate of the GGRF and the mission of most GBs to focus on proven, commercially viable technologies, such as solar panels and wind turbines, rather than high-risk, early-stage innovations. In counties where startups are more mature and have already achieved some level of market validation, GB loan activity likely signals to VCs that climate-tech startups in the same area represent lower-risk, high-potential investments, thereby generating a stronger crowding-in effect. Additionally, we find that the impact of GB investments is greater in counties where the public is more concerned about climate change and in areas with a higher concentration of Democratic voters. These results suggest that the presence of local public support and political alignment with climate initiatives amplifies the signaling effect of GBs, resulting in more pronounced private capital inflows into climate-tech startups.

Lastly, we conduct a round-level analysis to examine how VC rounds that coincide with GB investments impact outcomes such as startup valuation and exit returns. This analysis is conditional on startups that have already secured VC deals, enabling us to assess how GB investments influence the valuation and performance of climate-tech startups once they have received private funding. Our findings show that climate-tech startups in counties with active GB loans achieve higher valuations and exit returns compared to their non-climate counterparts, suggesting that GB investments enhance both the perceived market value and performance of these startups. Together with the DiD results, these findings indicate that GB investments not only attract private capital but also positively shape market perception and performance outcomes for climate-tech startups.

Collectively, our study shows that GBs are valuable institutions for advancing the green transition by attracting venture capital investment into climate-related startups. Not only do GBs leverage public capital to attract private investment in established technologies—such as solar panels and wind turbines—but they also indirectly catalyze investment in new climate-related technologies. The finding is consistent with GBs' shared mission of "de-risking" environmental projects and "complementing/unlocking" private capital for the projects, instead of substituting existing or yet-to-be-deployed capital.⁴ Moreover, it is particularly relevant to policymakers as the GGRF is poised to begin distributing \$27 billion for green investments through GBs. Also, our findings are relevant to policymakers outside the US, as other governments may consider a similar or alternative investment vehicles for climate-related financing.

This paper is the first to provide a comprehensive analysis of GBs and examine their role in fostering private investment to mitigate the adverse effects of climate change, thereby contributing to the growing literature on government investment in advancing the green transition. For instance, Kennedy et al. (2024) highlight how private investments and public grants target different types of startups, with varying levels of risk tolerance. Bellon, LaPoint, Mazzola, and Xu (2024) examine Residential Property Assessed Clean Energy (PACE) loans, finding that PACE adoption generates local fiscal income and enhances the resilience of the housing stock to climate impacts. Also, Flammer, Giroux, and Heal (2024) explore blended finance, where public and philanthropic funding mobilizes private capital for impactful sustainable investments. Lastly, Lanteri and Rampini (2022) model heterogeneous capital goods with varying energy needs and ages, concluding that financially constrained firms face challenges in adopting newer, cleaner technologies due to higher down payment requirements. We contribute to this literature by focusing on government-funded GBs and their impact on local green investment.

Our paper also contributes to the literature on impact investing and, in particular, VCs. Geczy et al. (2021) shows that few impact funds tie compensation to impact and maintain traditional financial incentives. This evidence suggests that VCs are unlikely to forgo returns for impact as even impact VCs' contracts are not linked to impact outcomes, which provide further motivation for our use of VC investment as our main outcome variable. Also, Barber, Morse, and Yasuda (2021) study the nonpecuniary utility derived from impact investing and Jeffers et al. (2024) analyze the risk-adjusted performance of VC impact funds. Furthermore, differentiating the types of private investment is critical, as studies show that private equity ownership can reduce pollution (Bellon, 2022) and foster innovation in clean technologies (Kumar, 2024).

Our work also extends the literature on the role of banksin facilitating the green transition.

⁴For example, one of the missions of Connecticut Green Bank is to leverage limited public resources to scale-up and mobilize private capital investment in the green economy of Connecticut: link with more details.

Most studies focus on private banks and their environmentally-oriented lending. For example, Giannetti, Jasova, Loumioti, and Mendicino (2023) show that banks engaging extensively in environmental discourse tend to lend more to "brown" industries, while banks with net-zero commitments have yet to reduce credit supply to these sectors or increase financing for renewables (Sastry, Verner, & Ibanez, 2024). Additionally, other research evaluates whether banks' ESG commitments align with their actual lending practices (Basu, Vitanza, Wang, & Zhu, 2022) and the relationship between environmentally-friendly banks and green firms (Degryse, Goncharenko, Theunisz, & Vadasz, 2023; Houston & Shan, 2022). Scholars have also explored constraints private banks face in supporting the green transition (Degryse, Roukny, & Tielens, 2020), the effects of carbon taxes on bank lending behavior (Laeven & Popov, 2023), and banks' exposure to climate transition risks (e.g., Martini, Sautner, Steffen, & Theunisz, 2023 and Jung, Santos, & Seltzer, 2023). Our study contributes by shifting focus to government-funded GBs and their distinctive role in catalyzing local green investments, with a particular emphasis on climate-focused startups.

Another strand of the sustainable finance literature examines how climate risk shapes credit allocation across financial sectors, including by banks (Cortés & Strahan, 2017, Ivanov, Kruttli, & Watugala, 2023, Kacperczyk & Peydro, 2022, Brown, Gustafson, & Ivanov, 2021), mortgage markets (Sastry, 2021), real estate (Baldauf, Garlappi, & Yannelis, 2020, Bernstein, Gustafson, & Lewis, 2019), and insurance (Taylor & Druckenmiller, 2022). Giglio, Maggiori, and Stroebel (2015) and Giglio, Maggiori, Rao, Stroebel, and Weber (2021) further discuss discount rates that reflect the long-term risks of climate change.

The remainder of the paper is organized as follows. Section 2 discusses the institutional backgrounds related to Green Banks and the GGRF. Section 3 provides a description of the data and summary statistics. Sections 4 outline the empirical approach, results, and additional tests. Finally, Section 5 concludes with a brief summary.

2. Institutional Background

2.1. What are Green Banks?

According to the Coalition for Green Capital, "[g]reen banks are mission-driven institutions that use innovative financing to accelerate the transition to clean energy and fight climate change." These Green Banks do not receive deposits and, unlike traditional financial institutions focused on maximizing profits, they prioritize deploying capital toward environmentally sustainable projects. Their mission is to address climate change and enhance resilience, often with a focus on benefiting low-income communities. The Coalition for Green Capital categorizes Green Banks as public, non-profit, and quasi-public institutions. Public Green Banks are fully owned by states or are part of a state agency. For instance, the New York Green Bank, a public Green Bank, was established on December 19, 2023, and received an initial capital of \$165.6 million from the New York State Energy Research and Development Authority (NYSERDA). The funding came from uncommitted funds of the NYSERDA Energy Efficiency Portfolio Standard (EEPS) I, System Benefits Charge (SBC) III, uncommitted utility EEPS funds, and NYSERDA Renewable Portfolio Standard (RPS) resources (State of New York Public Service Commission, 2013).

Non-profit GBs are incorporated as 501(c)(3) organizations, maintaining minimal ties with government entities. An example is the Colorado Clean Energy Fund (CCEF), which was established through a collaborative effort involving the Colorado Energy Office, the U.S. Department of Energy, and the Coalition for Green Capital. The CCEF received its initial funding as a 501(c)(3) nonprofit in 2018 from the State of Colorado. GBs can be classified as quasi-public if they are incorporated as non-profits but have substantial managerial control or oversight from a government entity. An example of a quasi-public Green Bank is the Connecticut Green Bank, the first Green Bank in the U.S. It was created in July 2011 through Public Act 11-80 by the Connecticut General Assembly. Overall, a common characteristic of almost all Green Banks is that their initial funding originated from a state government or agency.

A core aspect of Green Bank operations is the use of financing instead of grants. Green banks expect the capital they deploy to be repaid, creating a revolving pool of funds that maximizes the impact of each dollar invested. Thus, Green Banks invest in projects that are past the research and development stage, with very few exceptions, such as investing a small portion of their capital in incubators. This approach ensures lower investment risk and a direct contribution to clean energy adoption. Another significant feature of Green Banks is their ability to leverage private capital effectively, thereby amplifying their impact. Public-private partnerships have driven substantial growth in clean energy projects, resulting in significant investments.

In 2023, the Coalition for Green Capital (CGC) and its network of Green Banks facilitated over \$10.6 billion in public-private investment, representing a 130% increase from 2022. Since 2011, these Green Banks have invested \$9.25 billion and mobilized \$16.16 billion in private co-investment (as of December 31, 2023). Some of these investments include large renewable infrastructure projects (e.g., solar, wind), residential solar panels installations, and buildings' energy efficiency improvements. Notably, 26% of the capital invested in 2023, amounting to \$2.7 billion, was directed toward low-income and disadvantaged communities (Consortium, 2024).

One of the objectives of Green Banks is to reduce the cost of capital for clean energy projects by addressing perceived risks and inefficiencies of scale. They achieve this through tools such as credit enhancements, aggregation of small projects, and co-investment. For example, the Solar and Energy Loan Fund (SELF), one of the Green Banks within the CGC's network, secured a \$3 million grant from JPMorgan Chase's Housing Innovation Prize in 2023 to support energy-efficient affordable housing projects in Florida.

Other notable projects include those by Michigan Saves, a Green Bank that received a \$30 million grant from the Michigan Department of Environment, Great Lakes, and Energy to launch a Septic Replacement Loan Program. Additionally, Michigan Saves received \$1 million from the American Rescue Plan Act (ARPA) funds to create an incentive program for residents of the City of Sterling Heights to implement energy efficiency and renewable energy improvements (Consortium, 2024). These examples illustrate how Green Banks are contributing to the green transition in various regions and sectors, from housing and water infrastructure to solar energy and energy efficiency. Their financing models and ability to mobilize private capital in partnership with public funds make them valuable players in the transition to a low-carbon economy.

2.2. Green Bank Networks

The Coalition for Green Capital (CGC) is not the only network of Green Banks operating in the U.S. and receiving funding from the Greenhouse Gas Reduction Fund (GGRF) within the Inflation Reduction Act (IRA). Other networks that have been allocated funding include: Power Forward Communities (\$2 billion), Climate United Fund (\$7 billion), Opportunity Finance Network (\$2.3 billion), Inclusiv (\$1.9 billion), Justice Climate Fund (\$1 billion), Native CDFI Network (\$0.4 billion), and Appalachian Community Capital (\$0.5 billion). Excluding the Climate United Fund, several key differences exist between Green Banks within the CGC network and those in other networks, particularly in terms of green investment focus. For example, Power Forward Communities, Opportunity Finance Network, and Native CDFI Network historically lacked a clear mandate for green investments and will be incorporating green objectives for the first time after they receive funding through the GGRF. Similarly, Inclusiv did not have sustainability or climate-related goals prior to 2020. The Appalachian Community Capital was only recently established on August 16, 2024, and has not yet made any investments. There is some overlap between the CGC and the Justice Climate Fund. However, many of the banks not associated with CGC did not have explicit climate objectives until they applied for the GGRF.

The Climate United Fund is slightly different as it comprises Calvert Impact, Community Preservation Corporation, and Self-Help Credit Union. Together, they have raised and deployed more than \$30 billion across partners in a variety of sectors in all 50 states. Calvert Impact is a global nonprofit investment firm focused on "solutions that people and our planet need." The Self-Help Credit Union was chartered in 1983 and did not have a green investment focus until 2020, when its annual report first mentioned green investments. This included a net-zero building with solar panels for a community health center in Colorado.

Community Preservation Corporation (CPC), established in 1974 in New York City, launched a platform in 2008 "to promote energy and water conservation measures that improve the financial and physical quality of the buildings and communities in which we live and work." By 2015, CPC had financed more than 12,000 sustainable units and originated nearly \$2 billion in green lending. Relevant to our study, although CPC currently has a national footprint, as of 2018, its investments were concentrated in New York, Massachusetts, Connecticut, Pennsylvania, and New Jersey—all states where we have data from other Green Banks.

Lastly, Calvert Impact is considerably different from the other GBs. Specifically, Calvert Impact operates with a global presence and is not restricted to investing in, or continuing to invest in, a specific location. Unfortunately, we are unable to collect detailed investment data from Calvert Impact. This missing information may introduce measurement error, as counties that received funding from Calvert Impact could be mistakenly classified as counties with no GBs investment. This would potentially bias our estimates downward. In addition, since our analysis focuses on the extensive margin, the absence of data on Calvert Impact's investments in counties where other Green Banks are active should not affect our results.

2.3. Green Banks and Local Green Investment

The presence of government-funded green banks is expected to influence local green investment through several mechanisms. By providing targeted financing to projects that meet commercial readiness criteria, GBs may alleviate some of the perceived risks associated with investing in climate-focused startups without directly being directly involved in the deals. For venture capitalists (VCs), who are profit-driven and less likely to sacrifice returns for non-financial objectives, the availability of GB funding serves as a credible signal of long-lasting local government and private green investment and policy stability. This signal could make VCs more inclined to reassess the financial prospects of local climate startups, particularly if they perceive GB activity as indicative of a more favorable investment environment.

Another potential effect of GB activity is its influence on the local demand for green products and services. The establishment of GB-funded projects could stimulate broader adoption of climate-focused technologies, which in turn may benefit startups operating in these sectors. Increased demand may enhance the growth prospects of local startups, leading VCs to view these companies as better-positioned to achieve long-term profitability. If GB activity signals a stable and expanding market for green products and services, it could further strengthen the incentives for VCs to invest in climate startups.

3. Data and Summary Statistics

3.1. Green Banks

We collect information on Green Banks in the US using publicly available information from each banks' annual report or website.⁵ We focus our attention on the Coalition for Green Capital (current National Green Bank) since they were one of the largest recipients of funding of the GGRF and their objectives are strictly connected to investment in the green transition.

Specifically, we collect information on county-level loans issued for the following Green Banks: Abundant Power, California Alternative Energy and Advanced Transportation Finance Authority (CAEATFA), California Pollution Control Finance Authority (CPCFA), Colorado Clean Energy Fund (CCEF), Columbus Region Green Fund, Connecticut Green Bank, DC Green Bank, Delaware Sustainable Energy Utility, Efficiency Maine, Finance New Orleans, GO Green Energy Fund, Illinois Climate Bank (ICB), Maryland Clean Energy Center, Massachusetts Clean Energy Center, Montgomery County Green Bank, New Jersey EDA, New York City Energy Efficiency Corporation (NYCEEC), New York Green Bank (NYGB), Philadelphia Green Capital Corp, Rhode Island Infrastructure Bank (RIIB), Solar Energy Loan Fund (SELF), and Virginia Resources Authority (VRA).

For these banks, we are able to identify at least if the bank issued loans in year t in county c. For some of the banks, we also have information on the amount of investment as well as other impact measures, such as jobs created and GHG emission reduce. However, the availability of impact estimates is very limited at this time. The oldest Green Bank is the CPCFA, established in 1972, even though this agency was not explicitly defined as a Green

⁵We are grateful to the Connecticut Green Bank for sharing information not available on their reports.

Bank at the time. Note that the year of establishment is not necessarily the year in which the GB starts issuing loans. Table IA1 in the Internet Appendix reports the list of some of the GBs operating in the US, their year of establishment, type (public, quasi-public, or non-profit), and the state where they issue loans. We provide summary statistics for all three types of GBs, but focus our analysis on public and quasi-public Green Banks for a total of 12 GBs. We exclude non-profit banks as they have been established recently, they have a considerably lower investment volume, or operate in only one county (e.g., Abundant Power Group, Montgomery County Green Bank).

Figure 1 illustrates the geographical distribution of Green Bank lending activity. Counties are marked in blue if a Green Bank reported issuing at least one loan there between 2015 and 2023. We find that, on average, Green Bank loans are more commonly issued in counties with larger populations, slightly higher average incomes, higher house prices, and more Democraticleaning political preferences (Table 1). We also hand-collected information on the investment focus of the GBs. Seventeen of the 21 GBs are solely dedicated to green investment, while the remaining four have a more diversified portfolio that includes, for example, non-green infrastructure loans and loans to farmers. The primary focus of the GB investments is in energy efficiency and clean energy, including building efficiency projects such as heat pumps and insulation, as well as renewable energy installations like solar panels, wind turbines (both on- and offshore), and biomass facilities. Also, many of these banks aim to increase lending to socio-economically marginalized communities and small businesses. Specifically, they often include objectives to support low-income households and minority communities to promote a just and equitable green transition.⁶

3.2. Startups and Venture Capital Investment

Our sample consists of startups headquartered in the U.S. identified with data from PitchBook. This dataset has comprehensive coverage of various aspects of startup financing rounds, including details such as timing, stage (e.g., Seed, Series A, B, C, etc.), investment amount, and the identity of investors involved in each round. PitchBook further categorizes startups into "verticals" based on their technological orientation (e.g., FinTech, Nanotechnology, Software-as-a-Service, etc.). These verticals group startups into clusters that concentrate on a shared niche or specialized market.⁷ Our analysis specifically focuses on startups falling under the "Climate

⁶A description of the GBs investment focus is provide in Table IA2 in the Internet Appendix.

⁷A single vertical may be comprised of companies that span multiple industries. PitchBook explains the differences between verticals and industry classifications here: https://pitchbook.com/what-are-industry-verticals.

Tech" or "CleanTech" verticals.⁸ We consider VC financing rounds taking place from 2015 to 2023. To be included in our sample, a financing round must meet the following criteria: 1) it is explicitly identified in the PitchBook database as a "Venture Capital" round with at least one investor in the syndicate identified as a VC investor by PitchBook;⁹ 2) it must have non-missing data for deal size and deal date; and 3) it must involve the raising of new equity (debt-only and secondary-sale rounds are excluded). The final sample comprises 102,937 deals involving 51,158 startups, including a subset of 5,339 deals for 2,533 climate-related startups.

3.3. County Characteristics

The county-level economic data, including population, personal income, and unemployment rate, are collected from the U.S. Bureau of Economic Analysis (BEA) and the U.S. Bureau of Labor Statistics (BLS). We collect information on house prices from Zillow (Zillow Home Value Index or ZHVI). We use the 2014 Yale Climate Opinion Survey data and, in particular, the response to the question: "How worried are you about global warming?" to define the *Worried* indicator. This indicator equals one for counties where the percentage of respondents who state to be worried is greater than the median and zero otherwise.¹⁰ The county-level presidential votes are from the MIT Election Lab.¹¹ We define a Republican indicator equal to one if the presidential votes in county c are above the median and zero otherwise.

4. Results

4.1. Identification Strategy

Our sample period runs from 2015 to 2023, chosen for several reasons. First, 2015 marks the beginning of a significant resurgence in VC interest in green technologies. This period saw massive inflows of private capital into climate-tech startups, with investment growth exceeding 150% between 2015 and 2021 (Cornelli, Frost, Gambacorta, & Merrouche, 2023).¹² Also, prior

⁸Based on PitchBook's definition, the "Climate Tech" vertical includes "companies developing technologies intended to help mitigate or adapt to the effects of climate change. The majority of companies in this vertical are focused on mitigating rising emissions through decarbonization technologies and processes. Applications within this vertical include renewable energy generation, long duration energy storage, the electrification of transportation, agricultural innovations, industrial process improvements, and mining technologies, among others." Similarly, the "CleanTech" vertical includes "developers of technology which seeks to reduce the environmental impact of human activities or to significantly reduce the amount of natural resources consumed through such activities."

⁹This restriction excludes VC rounds financed purely by individuals, angel groups, accelerators/incubators, crowdfunding investors, etc.

¹⁰The possible responses are very worried, somewhat worried, not very worried, and not at all worried. We consider the first two responses as worried.

¹¹https://electionlab.mit.edu/data

¹²Prior to 2015, most VC investments in climate tech were concentrated in wind and solar technologies. However, many investors experienced significant losses, largely due to the capital-intensive nature of these technologies and their long payback periods, compounded by the impact of the Great Financial Crisis (Gaddy,

to 2015, many of the Green Banks did not exist or did not have a specific focus on the green transition (e.g., Virginia Resources Authority, Rhode Island Infrastructure Bank, and New Jersey Economic Development Authority). The policy landscape also shifted in 2015 with the signing of the Paris Agreement, which created a favorable environment for climate tech investments. Given these trends, 2015 is a natural starting point for examining the intersection of Green Bank loans and VC investment in climate tech startups.

Our primary econometric model examines the relationship between VC investment outcomes and the interaction of an indicator for Green Bank funding in the county where a startup is headquartered and an indicator for climate-tech startups. Specifically, we use a generalized staggered DiD estimator to compare changes in VC investment outcomes for climate-tech startups relative to non-climate-tech startups headquartered in counties that receive Green Bank funding with those in counties that do not. This strategy exploits variation driven by the staggered timing of Green Bank funding across counties and multiple time periods.

Formally, we estimate the following empirical specification:

$$y_{i,c,t} = \beta_0 + \beta_1 GB \ fund_{c,t} + \beta_2 GB \ fund_{c,t} \times Climate \ startup_i + \tau_i + \rho_{j,t} + \omega_{c,t} + \varepsilon_{i,c,t}$$
(1)

where startup *i*, operating in industry *j*, is headquartered in county *c*, in year *t*. We focus on an event window spanning four years before to four years after the startup's county receives Green Bank funding. *GB fund* is a dummy variable equal to one if the startup is located in a county that received funding from a Green Bank in the current year or in the previous four years, and zero otherwise. *Climate startup* is a dummy variable equal to one if the startup is labeled under the "Climate Tech" or "CleanTech" verticals in PitchBook, and zero otherwise. The standard errors are clustered at the headquarter county level to adjust for potential issues with grouped error terms as Green Bank funding is assigned at this geographic level (Gu, Huang, Mao, & Tian, 2022; Guernsey, John, & Litov, 2022).

We consider two sets of fixed effects in our analysis. First, we include startup, industry, county, and year fixed effects.¹³ Second, we implement a more stringent set of fixed effects (Acharya, Baghai, & Subramanian, 2014; Gormley & Matsa, 2016). These include startup fixed effects (τ_i), which control for unobserved, time-invariant characteristics specific to each startup that might influence VC investment outcomes, such as the startup's reputation or

Sivaram, Jones, & Wayman, 2017). As a result, the climate tech sector fell out of favor, with VC investment flows being redirected to other industries (van den Heuvel & Popp, 2023).

¹³Startup fixed effects subsume the main effects for *Climate startup*.

management quality. We also include industry-year fixed effects $(\rho_{j,t})$, which account for shocks or trends common to all startups within the same industry during a given year, such as industry-wide technological advancements or regulatory changes. Finally, county-year fixed effects $(\omega_{c,t})$ are used to control for local economic conditions or government initiatives that may vary across counties and years, ensuring that the effects of Green Bank funding are not confounded by other county-level influences.

4.2. Baseline Estimates

Table 3 reports the results of the DID estimation using Equation (1). The dependent variable in columns (1)-(3) is a binary indicator representing whether a startup received VC investment in a given year, while columns (4)-(6) use the natural logarithm of one plus the dollar amount of VC investment received. The results show that while Green Bank investments in a county has a positive and statistically significant effect on the likelihood of VC investment for all startups in that county, the effect is even stronger for climate-tech startups. Specifically, counties that receive Green Bank funding see an 8.5% to 11.6% increase in the probability of climate-tech startup deals relative to other types of startups. These results hold when restricting the analysis to states where we have information on Green Bank loan amounts in each county (columns (3) and (6)). In addition, the results are robust across different fixed effects specifications and remain consistent when using the continuous VC investment amount as the dependent variable.

To provide further robustness of the results, we replace the indicator for Green Bank funding with a continuous treatment variable that captures variation in the intensive margin of loans issued by Green Banks in a given county. Specifically, we define *GB fund amt* as the log of one plus the dollar amount of funding that a county, where the startup is located, receives from a Green Bank in the current year and the previous four years. We then estimate the DiD model in Equation (1) using this continuous treatment. The results, presented in Table IA3, show that counties with higher volumes of Green Bank funding see an increase in both the likelihood of VC deals and the dollar amount of VC investment in climate-tech startups. Overall, these findings underscore the effectiveness of Green Banks in mobilizing private capital for climate-focused ventures, supporting the policy goal of promoting green investment and sustainable development.

4.2.1. Dynamic Effects

Our identification strategy relies on the parallel-trends assumption, which posits that both climate-tech and non-climate-tech startups would exhibit similar trends in VC investment outcomes prior to Green Bank investments. To test for pre-trends, we estimate a dynamic version of Equation (1), focusing on the four years before and after Green Bank funding. As our treatment variable is staggered, we follow the approach employed in previous studies (Fuest, Peichl, & Siegloch, 2018; Smith, Yagan, Zidar, & Zwick, 2019) to estimate the dynamic treatment effects based on the intensity of treatment as follows:

$$y_{i,c,t} = \sum_{\substack{\ell=-5\\\ell\neq-1}}^{\ell=+5} \gamma_{\ell} GB \text{ fund intensity}_{c,t}^{\ell} + \sum_{\substack{\ell=-5\\\ell\neq-1}}^{\ell=+5} \lambda_{\ell} GB \text{ fund intensity}_{c,t}^{\ell} \times Climate \text{ startup}_{i}$$

$$(2)$$

$$+ \tau_{i} + \rho_{i,t} + \omega_{c,t} + \varepsilon_{i,c,t}$$

where

$$GB \text{ fund intensity}_{c,t}^{\ell} = \begin{cases} \sum_{s=-\infty}^{\ell} \Delta GB \text{ fund}_{c,t-s}, & \text{if } \ell = -5 \\ \Delta GB \text{ fund}_{c,t-\ell}, & \text{if } -4 \le \ell \le +4 \\ \sum_{s=\ell}^{\infty} \Delta GB \text{ fund}_{c,t-s}, & \text{if } \ell = +5 \end{cases}$$
(3)

The dynamic effects, λ_{ℓ} provide event-study estimates that capture changes in VC investment outcomes over time for climate-tech and non-climate-tech startups in counties receiving Green Bank funding. We normalize $\ell = -1$ as the reference period, with event time $\ell = 0$ indicating the year of Green Bank funding. To identify the dynamic effects during the event window, we bin the endpoints ($\ell = -5, +5$) according to Equation (3).

Our results do not reject the parallel-trends assumption, as shown in Figure 2. The dynamic effects indicate no significant differences in trends between climate-tech and non-climate-tech startups prior to Green Bank funding. Panel A shows that the likelihood of VC deals does not exhibit any pre-treatment differential response, and Panel B shows a similar pattern for the VC investment amount. In the years following Green Bank funding, we observe a notable increase in both VC outcomes for climate-tech startups, suggesting a positive and sustained impact of Green Bank funding. While it is possible that Green Banks target counties further along in the green transition, which could influence our results, we do not find evidence of pre-existing trends to substantiate this concern.

4.3. Signaling and the Inflation Reduction Act

The announcement of the Greenhouse Gas Reduction Fund (GGRF) within the Inflation Reduction Act signals that financing for green investments will be available for an extended period. Since these funds will be deployed through GBs, counties where GBs have already invested are at a significant advantage. However, because climate startups often focus on innovative technologies, only a few are likely to be directly funded by GBs through the GGRF. This expected lack of direct funding to startups supports the hypothesis that the effect is driven by signaling rather than a direct injection of funds. We find evidence for this in Table 4, which shows that after 2021, the year when the IRA began being discussed in Congress, counties with prior GB loans experienced an additional increase in both the likelihood of VC deals and the amount invested in climate startups. These results suggest that signaling plays a key role, though the analysis is limited by the short time period post-IRA.

4.4. Heterogeneity

In this section, we examine the heterogeneity in the impact of Green Bank funding by conducting cross-sectional tests based on startup and county characteristics. We augment Equation (1) by including triple interaction terms with variables that measure these characteristics.

In columns (1) and (2) of Table 5, we find that older climate-tech startups attract more VC investment when Green Banks make investments in the same county, compared to younger startups. This result aligns with the mandate of the GGRF and the mission of most Green Banks, which prioritize supporting proven technologies. By investing in counties with more mature startups, Green Banks signal to VCs that these startups are viable, lower-risk investment opportunities. Consequently, VCs are more likely to invest in these established companies, recognizing the Green Banks' endorsement of their market potential. In this context, Green Banks play a catalytic role by signaling VCs to channel private capital toward scaling proven technologies, rather than funding speculative or nascent innovations.

Columns (3) and (4) demonstrate that prior VC financing amplifies the effect of Green Bank funding. The positive and significant interaction between GB fund \times Climate startup \times Past VC financing indicates that climate-tech startups with a history of VC investment are more likely to attract additional VC funding when Green Bank investments are made in the same county. This result suggests that Green Bank activity provides an additional layer of institutional validation, reinforcing the credibility of startups that have already demonstrated their viability in the VC market. In doing so, Green Banks help facilitate the scaling of these startups by encouraging further investment.

In columns (5) and (6), we assess the moderating effect of public opinion on climate change using data from the Yale Program on Climate Change Communication (YPCCC) survey, which measures the percentage of adults in a startup's headquarter county who are worried about global warming (Howe, Mildenberger, Marlon, & Leiserowitz, 2015). Counties with a higher proportion of individuals expressing concern about climate change are likely to create a more favorable environment for climate-tech startups, as public opinion influences both policy decisions and market demand for climate solutions. The results show that Green Bank funding has a stronger effect on VC investment in climate-tech startups in counties where a larger share of the population is concerned about global warming. In these regions, Green Bank support aligns with public sentiment, likely boosting demand for climate-tech products and attracting further private investment.

In the last two columns of Table 5, we find that that in more Republican areas, where there may be less public and political support for climate initiatives, Green Bank funding has a more limited impact on attracting VC deals for climate-tech startups. This result is consistent those of Burt, Harford, Stanfield, and Zein (2023), who show that climate-related startups backed by Democrat VC partners tend to outperform those backed by non-Democrats, suggesting that political alignment influences the effectiveness of Green Bank funding in attracting private capital for climate-related investments.

4.5. Placebo Test

It is possible that federal government investment might have a similar impact as GBs. To test this hypothesis and further validate the channel driving the main results, we conduct a placebo test to examine whether federal government grants influence VC investment similar to Green Bank funding. Specifically, we first identify grants issued by the Environmental Protection Agency (EPA), Department of Energy (DoE), and Department of Agriculture (DoA) to startups in the Pitchbook dataset. Next, we limit our sample to counties with no GB investment to exclude that GBs are driving the results in the placebo test. Lastly, we define a county as treated (*Government grant=1*) if at least one startup has received funding from a government agency in the current year or in the previous four years.

The results in Table 6 show that government grants do not impact local VC investment or VC investment in local climate startups, as the coefficients on *Government grant* and the interaction between *Government grant* and *Climate startup* are not statistically different from zero. These findings suggest, unlike Green Banks, which explicitly aim to mobilize private capital and de-risk investments, traditional government grants appear insufficient to signal investment quality to VCs. This placebo test highlights the unique role of GBs in shaping private sector investment behavior in climate tech and fostering market-based scaling of climate technologies.

4.6. Additional Robustness Tests

We provide additional robustness to the results by replicating the main analysis using only the states in which the GBs have a clear green investment objective since their inception and we were able to verify the activity of each GB. These states include California, Connecticut, Florida, Illinois, Ohio, Maine, Maryland, Massachusetts, Pennsylvania, Rhode Island, New York, and New Jersey. The results reported in Table IA4 in the Internet Appendix are stronger than the main analysis. Specifically, GBs' loan activity in a county is positively related to the number of VC deals and investment amount in climate-tech startups.¹⁴

4.7. Round-level analysis

The DiD analysis thus far examines the determinants of VC financing for climate-tech startups, focusing on how Green Bank investments influence the likelihood of securing a deal. In this section, we conduct round-level analysis conditional on startups that have already secured VC financing. Specifically, we explore differences in round-level outcomes, such as startup valuation and exit performance, when the financing round coincides with Green Bank investments in the same county. We estimate the following regression model:

$$y_{i,r,c,t} = \beta_0 + \beta_1 GB \text{ fund round}_{c,t} + \beta_2 GB \text{ fund round}_{c,t} \times Climate \text{ startup}_i + \gamma X_i$$

$$+ \tau_i + \omega_c + \mu_t + \delta_s + \varepsilon_{i,r,c,t}$$

$$(4)$$

for startup i, in VC round r, headquartered in county c, in year t. The outcome variables, defined below, include measures of startup valuation and exit performance. We define a VC round as coinciding with Green Bank investment if it occurs in the year immediately following the Green Bank funding. Specifically, *GB fund round* is a dummy variable equal to one if the startup is located in a county that received Green Bank funding in the year prior to the VC round, and zero otherwise. This approach aligns with the typical time horizon over which VCs make investment decisions. For example, Gompers, Gornall, Kaplan, and Strebulaev (2020, p. 177) find that "VCs devote substantial resources to conducting due diligence on (i.e., investigating) their investments. The average deal takes 83 days to close; the average

¹⁴In unreported results, we find that the estimates remain qualitatively unchanged when excluding California.

firm spends 118 hours on due diligence over that period." Therefore, VCs are more likely to base their investment decisions on recent information, making the prior year's Green Bank investment more relevant than those made further in the past.

We include a set of startup-level control variables, denoted by X_i , in line with the existing literature (Burt et al., 2023; Pham, Rezaei, & Zein, 2023). Due to data limitations, we are constrained in capturing a wide range of startup attributes. Specifically, we control for the startup's age, whether it received VC financing in the past five years, and whether it was generating revenue at the time of the current VC financing round. These variables are intended to capture a startup's level of maturity beyond what is implied by its current financing stage. Also, variations in outcome variables may be influenced by investor characteristics; for instance, a prominent lead VC can attract other investors, potentially boosting the startup's valuation and exit performance. To account for this, we include controls for the lead VC's age and its investment activity over the past five years. However, as these startup-level controls are available only for a subset of the sample, we estimate Equation (4) with and without these variables.

We include in the model several types of fixed effects that account for many confounding factors influencing round outcomes. Startup fixed effects (τ_i) control for time-invariant characteristics specific to each startup, such as inherent quality, founding team strength, or business model. County fixed effects (ω_c) capture differences across geographic locations that may influence VC availability and investor interest, including local economic conditions and regulatory environments. Round year fixed effects (μ_t) control for time-specific factors, such as macroeconomic trends and policy changes, that impact all startups in a given year. Finally, VC round fixed effects (δ_r) account for differences in funding stages (e.g., Seed, Series A, Series B) that reflect the startup's development phase and typical financing needs at each stage.

In Table 7, we examine outcome variables related to the valuation of the startup at the VC financing round. These variables include the log of the deal size $(ln(Deal \ size))$, the post-money valuation of the startup $(ln(Post \ valuation))$, whether the round was classified as an "up" round (i.e., an increase in valuation relative to previous rounds), and the log of startup revenue at the time of the VC round (ln(Revenue)). The positive and significant coefficients on $GB \ fund \ round \ \times \ Climate \ startup$ indicate that VC rounds coinciding with Green Bank investments enhance the perceived valuation of climate-tech startups. Together with the prior results, this finding suggests that Green Bank investments not only increases the likelihood of attracting private capital but also raises the market valuation of climate-tech

startups that receive such funding. These results support the signaling mechanism, as Green Bank investments likely convey to VCs the long-term market potential for climate-related innovations, leading to higher valuations and greater financial commitments during the round.

Next, we perform a round-to-exit performance analysis by restricting the sample to firms for which we can observe a full set of rounds until an exit event. We use two outcome variables to assess round-level performance: (i) the round-to-exit multiple, and (ii) the annualized round-to-exit return. The round-to-exit multiple is calculated as the exit valuation divided by the post-money valuation at the current round. For IPO exits, we use the pre-money IPO valuation (i.e., the company's value before raising public capital) as the exit valuation. For M&A exits, we use the reported acquisition deal value. For liquidated startups, the exit multiple is set to zero.¹⁵ The round-to-exit return is an annualized return associated with the round-to-exit multiple, based on the holding period measured as the number of days between the current round and the exit date. Liquidated deals are assigned a return of -100%.

In Table 8, we estimate Equation (4) using the round-to-exit multiples and returns associated with each specific VC round. To control for major outliers, we first winsorize returns and multiples at the 1% level. Additionally, because returns and exit multiples are highly skewed but can include zero values, we apply the inverse hyperbolic sine (asinh) transformation to these variables in all specifications.¹⁶ The negative and significant coefficients on *GB fund round* across all specifications indicate that VC rounds coinciding with Green Bank funding are associated with lower exit multiples and returns for non-climate-tech startups. In contrast, the positive and highly significant interaction term *GB fund round* \times *Climate startup* suggests that VC rounds coinciding with Green Bank investments have a strong positive impact on the exit performance of climate-tech startups. Thus, VC rounds associated with Green Bank investments not only increase the perceived valuation of climate-tech startups but also generate higher returns for investors, providing financial benefits for those who participate in these rounds.

5. Conclusion

This paper investigates the role of government-funded GBs in stimulating local green investment, focusing on climate-related startups. This is the first study to focus on GBs and, for this reason, we provide the first description of these institutions, highlighting their investment

¹⁵We classify startups as liquidated if Pitchbook directly identifies these firms as exited through liquidation or bankruptcy, or if Pitchbook lists the company's current status as "out of business".

¹⁶Coefficients from regressions using asinh-transformed variables can be interpreted similarly to those from log-transformed data. However, asinh has the advantage of being defined at zero.

focus, location of operation, and incorporation type. In addition to the description of the institutions, we examine their impact on local green investment. Leveraging the staggered loan activity of Green Banks over time and geography and the introduction of the GGRF within the Inflation Reduction Act, we provide evidence on the positive impact of GBs on the green transition. Our findings indicate that counties receiving GB funding experience a significant increase in both the likelihood of VC deals and the amount of investment in climate-related startups. These results are robust when using binary and dynamic treatments, across various fixed-effects specifications, and samples. The results do not seem to be driven by existing local trends before the GB loans.

We hypothesize that the introduction of the GGRF serves as a substantial signal to investors about the availability of funds for green projects through GBs. Consistent with this hypothesis, we observe that after the Inflation Reduction Act was introduced in Congress, VC funding for climate-related startups increased in counties with GB loans. This suggests that venture capitalists perceive GB lending activities as an opportunity to invest in local climate startups, possibly due to reduced information asymmetry or enhanced credibility of these startups.

Our exploration of heterogeneity across regions reveals that the impact of GBs is more pronounced in areas with higher concern about climate change and in counties that lean more Democratic. Additionally, we find that older startups and those with prior VC financing benefit the most from GB presence. This aligns with the mandates of the GGRF and the mission of many GBs to invest in established technologies such as solar panels and wind turbines. Lastly, our analysis at the investment round level shows that climate startups in counties with GB loans exhibit better performance across various measures, indicating that GBs not only facilitate access to capital, but also contribute to the overall success of these ventures.

These findings have significant implications for policymakers and practitioners. They highlight the effectiveness of government-funded Green Banks in mobilizing private capital toward climate-related investments, thereby helping to bridge the substantial funding gap required to meet global warming targets. The evidence suggests that GBs play a crucial role in enhancing regional economic resilience and accelerating the transition to a low-carbon economy by acting as catalysts for green innovation at the local level.

Figure 1

Green Banks across the U.S.

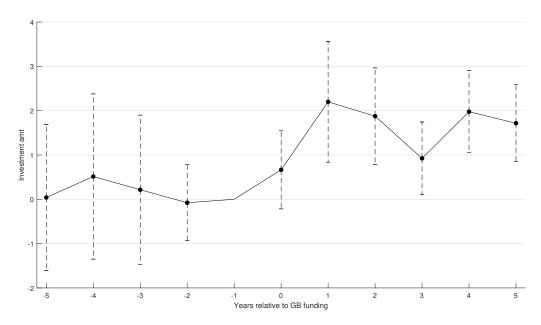

This figure reports in blue the counties that received at least one loan from the Green Banks that report county-level activity.

Panel A: Pretrends when the outcome variable is VC deal

Panel B: Pretrends when the outcome variable is Investment amt

This figure plots the event study estimates and corresponding 95% confidence intervals according to the specification in Equation (2). We focus on an event window of four years before to four years after the county where the startup is located receives funding from a Green Bank. We bin up event dummies at the endpoints of the event window following Equation (3). Event year $\ell = -1$ is the omitted category, implying that all coefficient estimates are relative to this year.

Summary statistics split by counties with and without Green Banks.

	Counties with GB	Counties without
	Activity	GB Activity
Population	350,268	73,159
Income	53,593	44,914
Republican Votes (%)	53%	68%
White Pop. (%)	73%	78%
Black Population (%)	9%	9%
Minority Population (%)	27%	22%
Worried about Climate Change (%)	60%	54%
House Price	$280,\!670$	168,358
N. Counties	362	$2,\!696$

This table reports summary statistics for counties with and without Green Bank activity.

Table 2Startup sample description.

Impact of Green Bank funding on venture capital investment in climate-tech startups.

VC deal is a dummy variable equal to one if the startup receives VC investment in a given year, and zero otherwise. Investment amt is the log of one plus the dollar amount of VC investment the startup receives in a given year. GB fund is a dummy variable equal to one if the startup is located in a county that received funding from a Green Bank in the current year or in the previous four years, and zero otherwise. Climate startup is a dummy variable equal to one if the startup is labeled under the "Climate Tech" or "CleanTech" verticals in PitchBook, and zero otherwise. Columns (3) and (6) restrict the sample to startups located in California, Connecticut, Illinois, New York, and Virginia. Industry fixed effects are based on PitchBook's industry classification for startups. The sample period is 2015 to 2023. Robust t-statistics based on standard errors clustered at the county level are reported in parentheses. *, **, and *** indicate significance at the 10%, 5%, and 1% level, respectively.

VC deal is a dummy variable equal to one if the startup receives VC investment in a given year, and zero otherwise. *GB* fund is a dummy variable equal to one if the startup is located in a county that received funding from a Green Bank in the current year or in the previous four years, and zero otherwise. *Climate* startup is a dummy variable equal to one if the startup is labeled under the "Climate Tech" or "CleanTech" verticals in PitchBook, and zero otherwise. *Startup* age is the age (in years) of the startup based its founding year according to PitchBook. *Past VC financing* is a dummy variable equal to one if the startup received VC financing in the previous five years, and zero otherwise. *High worried* is a dummy variable equal to one if the startup received VC financing to the Yale Program on Climate Change Communication survey) is above the median for a given year, and zero otherwise. *High Rep* is a dummy variable equal to one if the percentage of Republican votes in the county where the startup is located is above the median for a given year, and zero otherwise. Industry fixed effects are based on PitchBook's industry classification for startups. The sample period is 2015 to 2023. Robust *t*-statistics based on standard errors clustered at the county level are reported in parentheses. *, **, and *** indicate significance at the 10%, 5%, and 1% level, respectively.

Table 6Placebo test.

Dep. variable: VC deal	(1)	(2)
Government grant	0.027	0.018
	(0.98)	(0.34)
Government grant \times Climate startup	0.008	-0.049
	(0.20)	(-0.71)

Year F.E.	Yes	No
Industry \times Year F.E.	No	Yes
County \times Year F.E.	No	Yes
Observations	10,831	10,167
R^2	0.04	0.05

VC deal is a dummy variable equal to one if the startup receives VC investment in a given year, and zero otherwise. Government grant is a dummy variable equal to one if the startup receives a grant from either the Environmental Protection Agency (EPA), Department of Energy (DoE), or Department of Agriculture (DoA) in the current year or in the previous four years, and zero otherwise. Climate startup is a dummy variable equal to one if the startup is labeled under the "Climate Tech" or "CleanTech" verticals in PitchBook, and zero otherwise. The sample consists of startups in the same counties and same PitchBook industries as those that receive government grants. We exclude all startups that located in a county that ever received funding from a green bank. Industry fixed effects are based on PitchBook's industry classification for startups. The sample period is 2015 to 2023. Robust t-statistics based on standard errors clustered at the county level are reported in parentheses. *, **, and *** indicate significance at the 10%, 5%, and 1% level, respectively.

Round-level analysis: startup valuation.

 $ln(Deal\ size)$ is the log of the dollar amount of the deal size of the VC round. $ln(Post\ valuation)$ is the log of the post-money valuation of the startup. Up round is a dummy variable equal to one if the round is classified as an "Up" round according to PitchBook, and zero if classified as a "Flat" or "Down" round. ln(Revenue) is the log of the startup's revenue at the time of the VC round. *GB* fund round is a dummy variable equal to one if the startup is located in a county that received funding from a Green Bank in the year prior to the VC round, and zero otherwise. *Climate startup* is a dummy variable equal to one if the startup is labeled under the "Climate Tech" or "CleanTech" verticals in PitchBook, and zero otherwise. *Past VC financing* is a dummy variable equal to one if the startup received VC financing in the previous five years, and zero otherwise. *Startup age* is the age (in years) of the startup based its founding year according to PitchBook. *Established operation* is a dummy variable equal to one if the startup is classified as "Generating Revenue" or "Profitable" in a given round, and zero otherwise. *VC age* is the age (in years) of the lead VC investor based its founding year according to PitchBook. *VC past investments* is the log of one plus the number of investments made in the previous five years by the lead VC investor before the current round. The sample period is 2015 to 2023. Robust t-statistics based on standard errors clustered at the county level are reported in parentheses. *, **, and *** indicate significance at the 10%, 5%, and 1% level, respectively.

Round-level analysis: startup exit performance.

Dep. variable:	Exit n	Exit multiple		return

$\frac{R^2}{2}$	0.81	0.81	0.90	0.89

Exit multiple is the inverse hyperbolic sine transformation of the round-to-exit multiple of a deal. The round-to-exit multiple is defined as the exit valuation scaled by post-money valuation at the focal round. For an IPO exit, we use the pre-money IPO value as the exit valuation. For M&A exits, we take the reported deal acquisition value as the exit valuation. For liquidated startups, the exit multiple is zero. Exit return is the inverse hyperbolic sine transformation of the annualized round-to-exit return of a deal. The round-to-exit return is annualized based on the holding period of the number of days between the focal round and the exit date. Liquidated deals are assigned a return of -100%. GB fund round is a dummy variable equal to one if the startup is located in a county that received funding from a Green Bank in the year prior to the VC round, and zero otherwise. Climate startup is a dummy variable equal to one if the startup is labeled under the "Climate Tech" or "CleanTech" verticals in PitchBook, and zero otherwise. Past VC financing is a dummy variable equal to one if the startup received VC financing in the previous five years, and zero otherwise. Startup age is the age (in years) of the startup based its founding year according to PitchBook. Established operation is a dummy variable equal to one if the startup is classified as "Generating Revenue" or "Profitable" in a given round, and zero otherwise. VC age is the age (in years) of the lead VC investor based its founding year according to PitchBook. VC past investments is the log of one plus the number of investments made in the previous five years by the lead VC investor before the current round. The sample period is 2015 to 2023. Robust t-statistics based on standard errors clustered at the county level are reported in parentheses. *, **, and *** indicate significance at the 10%, 5%, and 1% level, respectively.

New York Green Bank	2013	Public	New York
Philadelphia Green Capital Corp	2016	Quasi-public	Pennsylvania
Rhode Island Infrastructure Bank	1989	Quasi-public	Rhode Island
Solar Energy Loan Fund (SELF)	1995	Non-profit	Florida
Virginia Resources Authority	1984	Public	Virginia

This table reports the year of establishment and type of the Green Banks analyzed in the paper.

Table IA2Green Banks' Investment Focus.

Green Bank	Only Green In- vestments?	Environmental Investment Focus	Sector Focus	Social Investment Focus
Abundant Power Group	Yes	Energy Efficiency & Clean Energy	Infrastructure, building, agriculture, methane capture	N/A
California Alternative Energy and Advanced Transportation Finance Authority	Yes	Energy Efficiency & Clean Energy	Residential/commercial buildings, lithium bat- teries	N/A
California Pollution Control Finance Authority	No	Waste control	Water, landfills, compost, recycling	Small business & economically dis- advantaged community support
Colorado Clean Energy Fund	Yes	Energy Efficiency & Clean Energy	Residential/commercial/municipal buildings, industrial, agricultural, solar, heat pumps	Affordable housing
Columbus Region Green Fund	Yes	Clean Energy	Solar	Focus on rejected borrowers and disproportionately impacted by cli- mate change
Connecticut Green Bank	Yes	Energy Efficiency & Clean Energy	Residential/commercial/municipal buildings, industrial, agricultural	Goal of 40% investment in vulnera- ble communities
DC Green Bank	Yes	Energy Efficiency & Clean Energy	Residential/commercial buildings, industrial, infrastructure	Favor low-to-moderate income households
Delaware Sustainable Energy Util- ity	Yes	Energy Efficiency & Clean Energy	Residential/commercial buildings, agricultur- al/infrastructure	Programs for low-income house- holds
Efficiency Maine	Yes	Energy Efficiency & Clean Energy	Residential/commercial/municipal buildings	Low-income, small-business fo- cused
GO Green Energy Fund	Yes	Clean Energy	Solar	Low-to-moderate income communi- ties, minority-focused
Illinois Climate Bank	Yes	Energy Efficiency & Clean Energy	Solar, wind, commercial buildings, agriculture, clean water	
Maryland Clean Energy Center	Yes	Energy Efficiency & Clean Energy	Solar, wind, biomass	N/A
Massachusetts Clean Energy Cen- ter		Energy Efficiency & Clean Energy	Buildings, solar, wind, transportation	Diversity, equity, inclusion, and en- vironmental justice
Montgomery County Green Bank	Yes	Energy Efficiency & Clean Energy	Residential/commercial buildings, solar	N/A
New Jersey Economic Development Authority	No	Clean Energy	Solar, offshore wind	Équitable
New York City Energy Efficiency Corporation	Yes	Energy Efficiency & Clean Energy	Residential/commercial buildings, solar	Equitable
New York Green Bank	Yes	Energy Efficiency & Clean Energy	Residential/commercial buildings, infrastruc- ture, solar, wind, storage, transportation	N/A
Philadelphia Green Capital Corp	Yes		Residential/commercial buildings, solar	Improve public health, alleviate poverty, promoting economic devel- opment
Rhode Island Infrastructure Bank	No	Energy Efficiency & Clean Energy	Solar, wind, residential/commercial buildings, infrastructure, climate resilience	N/A
Solar Energy Load Fund (SELF)	Yes	Energy Efficiency & Clean Energy, Climate Resilience		Low and moderate income house- holds
Virginia Resources Authority	No	Energy Efficiency & Clean Energy	Solar, wind, residential/commercial buildings, infrastructure, agriculture, climate resilience	N/A

This table reports the investment characteristics of Green Banks.

VC deal is a dummy variable equal to one if the startup receives VC investment in a given year, and zero otherwise. Investment amt is the log of one plus the dollar amount of VC investment the startup receives in a given year. GB fund amt is the log of one plus the dollar amount of funding that a county, where the startup is located, receives from a Green Bank in the current year and in the previous four years. Climate startup is a dummy variable equal to one if the startup is labeled under the "Climate Tech" or "CleanTech" verticals in PitchBook, and zero otherwise. Columns (3) and (6) restrict the sample to startups located in California, Connecticut, Illinois, New York, and Virginia. Industry fixed effects are based on PitchBook's industry classification for startups. The sample period is 2015 to 2023. Robust t-statistics based on standard errors clustered at the county level are reported in parentheses. *, **, and *** indicate significance at the 10%, 5%, and 1% level, respectively.

GB fund is a dummy variable equal to one if the startup is located in a county that received funding from a Green Bank in the current year or in the previous four years, and zero otherwise. Climate startup is a dummy variable equal to one if the startup is labeled under the "Climate Tech" or "CleanTech" verticals in PitchBook, and zero otherwise. Columns (1) and (3) exclude the following states: District of Columbia, North Carolina, Delaware, Colorado, Texas, Michigan, Virginia, New Jersey, and Louisiana. Columns (2) and (4) exclude the previous states and California. Industry fixed effects are based on PitchBook's industry classification for startups. The sample period is 2015 to 2023. Robust t-statistics based on standard errors clustered at the county level are reported in parentheses. *, **, and *** indicate significance at the 10%, 5%, and 1% level, respectively.
